ABSTRACT

This research study investigates the perceptions of a low income population in North Nashville, Tennessee. The specific purposes were to describe demographic and social-psychological characteristics of the population, as well as the population's perceptions and knowledge of health problems and facilities. The information was collected through interviews. A random sample of households was selected, and 108 interviews were completed (88 Negro and 20 white households). The Negro and Caucasian groups within the sample were shown to have rather different demographic characteristics; the Negro group, for example, was somewhat younger and slightly larger. The two groups were also found to report different patterns of health problems and treatment sought; the frequency of reported health problems, for example, was higher for whites. In both groups, health problems were most frequently attributed to unknown causes. The treatment of choice was to consult a physician. Payment by the individual for treatment was more likely for those in higher occupational levels, from 20 to 40 years old, and Negroes. Behavior in response to perceived health problems can be viewed as reflective of the responses and alternatives available to people. (Not available in hard copy due to marginal legibility of original dccument.) (Author/JW)

PREFACE

This is a sociological study which gives an exciting glimpse into the health related facets of the lives of a group of 323 people who make up 108 families living in and representing an inner-city pocket of poverty. This twenty-odd square miles in Nashville is largely run down with over half the dwellings in a state of ill repair. The area includes much of the worst of downtown Nashville -- wholesale and warehouse areas with the usual railway lines, livestock processing plants and farmers' markets. On the positive side, and what probably makes this area different from typical inner-city slums, is the fact that the area includes two medical schools and teaching hospitals plus two large church-sponsored general hospitals, not to mention a large new public health center on its western fringe.

What are the health problems, practices and knowledge of people living in this tract? Drs. Mercer and Newbrough, plus their staff, interviewed these 108 families to find answers to this question. They amassed a rich load of information which should be invaluable, not only to the Meharry Medical College as a basis for expanding its community health service, but also more generally to the fields of sociology and medicine. It is heartening to find examples such as this of professions and agencies developing programs based upon scientific evidence rather than beliefs and suppositions.

While there is clear evidence that the sample is poorly educated, poorly housed and poorly financed, they do appear to be less disadvantaged in terms of health services. The average incidence of health problems was 1.4 per household per year. When problems arose, they went to the

physicians and hospitals rather than rely on healers, home remedies and patent medicines dispensed by the local druggist. It was interesting to note that 62 percent of the Negroes in contrast to only 26 percent of the whites paid for medical services from their own resources. In examining the nature of the population, one discovers that there were fewer children and more old folks among the limited sample of Caucasian families. This may well indicate that Medicare is having its effects.

The persons interviewed in this study were not as aware of public health services, including child care centers, as one would wish.

(Whether a sample of individuals of higher socio-economic class in the community would be better informed cannot be answered from this study since no contrast group was interviewed.) Investigators found people to be quite knowledgeable about the availability of the teaching and church-affiliated hospitals in the community and used them a good deal, especially in emergencies. They also saw the church as a place to go for help in times of illness. One would wish especially that the people were tetter apprised of health services in the community supported by the taxpayer. As Mercer and Newbrough point out, equally as important as setting up health services, is an effective program to inform the people shout these services and their availability. Clearly health education is a community and professional responsibility and probably cannot be done alone at school with only school-aged children involved.

Finally, this investigation is a landmark in cooperation. It involved two major units in the Nashville University Center in that the study was carried out under a contract between Peabody College and the Meharry Medical College. Too, it involved cooperation between two units

of Peabody's John F. Kennedy Center for Research on Education and Human Development, namely the Center for Community Studies and the Institute on Mental Retardation and Intellectual Development. More important is the fact that the study involved the collaborative efforts of persons in Sociology, Psychology and Medicine. As is almost always the case, the success of this project rests on the professional and personal qualities of its co-directors, Dr. Mercer and Dr. Newbrough.

Lloyd M. Dunn, Ph.D. Director, IMRID

Background and Acknowledgements

The project reported here was carried out under a contract between Meharry Medical College and the Center for Community Studies, an affiliate of the John F. Kennedy Center, Peabody College. The Center for Community Studies and the Institute on Mental Retardation and Intellectual Development joined forces to conduct the project. It was designed to collect information about the perceived health problems of a population in North Nashville and the treatment which the people sought. From this can be derived estimates of amount of illness and infirmity which the people experience. These estimates, coupled with views about resources for help, focus areas of emphasis which might be required in an outreach or public education program of a neighborhood health program.

The directors of the project wish to acknowledge with appreciation the assistance of the staff and the interest and support of the cooperating agencies. Staff for the project were:

Charles V. Mercer, Co-Director

J. R. Newbrough, Co-Director

Susan Watson, Assistant

Joseph R. Cardillo, Interviewer

Dan W. Davis, Interviewer

Richard Gibbs, Interviewer

Lloyd B. Greig, Interviewer

THE NORTH NASHVILLE HEALTH STUDY: RESEARCH INTO THE CULTURE OF THE DEPRIVED

"North Nashville" is an area of approximately two hundred city blocks or twenty odd square miles which, by almost any standard criteria, is a poverty area. For example, in 1960 only one-third of the population 25 years old and over had more than an eighth grade education; one-half of the occupied dwelling units were classified as "deteriorating" or "dilapidated"; and over sixty percent of the families of the area had an income of less than \$3,000 a year. Included in the vast array of problems which are found in such areas are conditions which are not conducive to good health; limited knowledge of appropriate behavior to adopt in reaction to health problems; and inadequate resources and facilities for the proper handling of such problems. In response to this situation, Meharry Medical College of Nashville is planning community health services which will serve this area of Nashville.

In planning any ameliorative program the three most common types of information used deal with (1) an objective description of the current state of the problem, (2) a projected ideal state and, finally, (3) some reasonable series of activities which will help to change the present into the ideal. For many programs this is sufficient, particuarly if the perception of the present state held by the planners is shared by the population to be benefitted or if implementation can be

^{1.} U. S. Census of Population and Housing: 1960. Unpublished Enumeration District Tabulations.

^{2.} Ibid.

 ¹bid.

accomplished with an element of coercion. When such programs are built on an assumption of shared perception or voluntary utilization by the population, a fourth type of information should be included in the planning.

This fourth category involves an empirical assessment of the population's perception of the problem and, if this perception is not similar to that held by the planners, the current state of the population's knowledge and reaction must be ascertained. The purpose of this study is the development of a body of information which will serve this fourth function in the process of facility planning.

Objectives

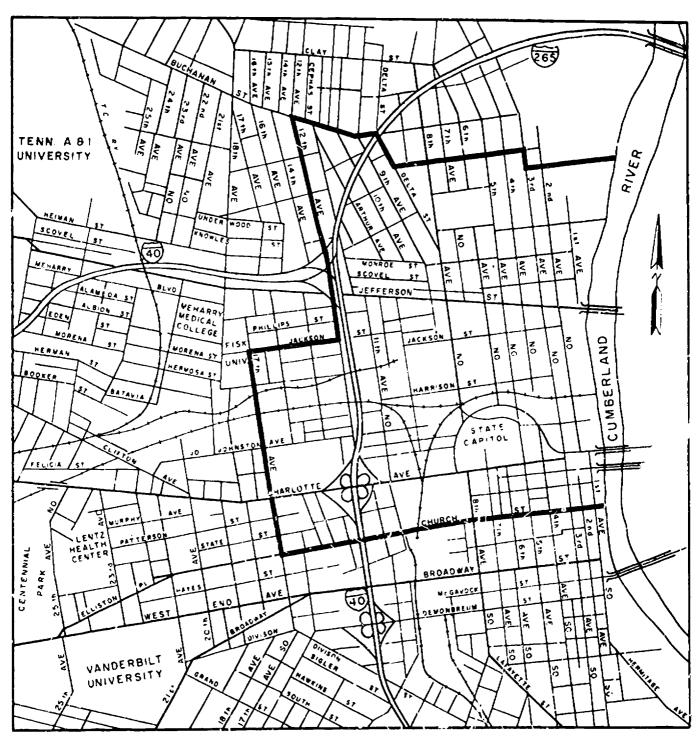

The specific objectives of the North Nashville Health Study were to obtain reliable estimates of

- 1) pertinent demographic characteristics of the population;
- 2) the composition of households in the area;
- 3) the current health problems as perceived by the population;
- 4) the population's perception of "causes" of health problems;
- 5) the various reactions or behaviors adopted in response to health problems;
- 6) the population's knowledge of available facilities for treatment;
- 7) the problems encountered in obtaining treatment or assistance and the interrelationships among these seven categories of variables.

While there are some very sound bases for estimating the current health state of this population, the successful establishment of a

Boundaries Of The Study Area

voluntary health facility depends upon such a facility being viewed by the population as having some relevancy in their lives. This may require some public education programs, cooperation with existing agencies now in contact with the population or other means of reaching the people. Whatever is done must be based, to some extent, on the existing situation of the area.

Procedures

In attempting to assess the present health states as perceived by representative members of the population, it was necessary to develop a questionnaire which would elicit responses in terms and concepts which were meaningful for the population but which would also be appropriate for a generalized description of the area. For this reason, a semi-structured instrument was developed. The health questions structure the categories of responses but are "open ended" so that specific answers could reflect the terminology in use in the population.

The questionnaire is divided into four basic parts: 1) household and demographic data; 2) health problems encountered over the past year, perceived causes and reactions to them; 3) awareness of, use of and evaluation of various sources of assistance; 4) general attitude and behavior questions which are relevant to health problems. A copy of the questionnaire used can be found in Appendix B.

For purposes of sampling, the population of interest was defined as those persons whose normal place of residence was in a household in the designated area (see Page 3 and Appendix A). At the outset, the

exact number of interviews to be obtained was not determined so the sampling procedures were planned to allow for expansion if desired.

Using 1960 Census of Housing Block Statistics for Nashville,
Tennessee, the city blocks of the area were sequentially arrayed by
block number within sequentially arrayed census tracts. The number
of occupied dwelling units in each block was automatically utilized to
weight a block's probability of inclusion in the sample. The occupied
dwelling units within each block were arbitrarily assumed to be numbered,
for sampling purposes, starting from a constant point (the northeast
corner of the block) in a clockwise direction. The number of occupied
dwelling units was accumulated through the array of blocks to a total
of 4,502 occupied dwelling units in 1960.

A series of random numbers between 1 and 4,502 were selected and maintained in sequence of selection so that the ultimate sample, regardless of size, would be, in effect, a random sample. These random numbers designated specific households of specific blocks to be included in the survey. The designated blocks were then inspected to determine the current number of occupied dwelling units in the block and the addresses of all households in the block. From this, the address of each household to be included in the sample was obtained.⁴

The interviewing was done by six medical students from Meharry Medical College and three psychology graduate students from George Peabody College. All of the interviewers had interviewing experience. They were given one orientation and training session. 5 Following this

^{5.} See J. Stacy Adams, <u>Interviewing Procedures</u>: <u>A Manual for Survey Interviewers</u>. Chapel Hill: The University of North Carolina Press, 1958.

^{4.} For an elaboratic of procedures used, see John Monroe and A. L. Finkner, The Handbook of Area Sampling. Philadelphia: Chilton Company, 1959.

session each interviewer took at least three trial interviews, using an earlier version of the questionnaire. In addition to training, this also served as a pre-test of the data collection instrument. Following these trial interviews, a conference with all personnel provided a basis for minor revisions in the questionnaire. At this point all interviewers were provided with specific household addresses from which they were to obtain an interview. The interviewers were instructed not to make substitutions in the event an interview could not be obtained from a designated household. A summary of the results of the field work is presented in Table 1.

Following an editing of the questionnaires, the data were coded for eighty-column punch cards from which tabulation and statistical analyses could be made by use of computers and other data processing equipment. A copy of the code used can be found in Appendix C.

CHAPTER II

Description of the Sample

The 108 interviews represented households containing 323 individuals, giving an average household size of 3.0 individuals. The racial composition of the households is 81.5 percent Negro and 18.5 percent white, and of individuals, 85.8 percent Negro and 14.2 percent white. The sex ratio of the sample is somewhat higher than was expected, there being 130 females to every 100 males.

There is every reason to believe, on the basis of sample design, that the sample is representative of the area. However, it seems advisable to offer some hypotheses concerning the figures above. In 1960, 72 percent of the area's population was Negro, while the sample percentage is 85.8. This difference may be due, in part, to sampling variation, i.e., the fact that any sample is likely to deviate to some degree from the characteristics of the parent population. It may, however, reflect selective migration into and out of the area. The total population of the area has been relatively stable, perhaps declining slightly. The sample figures would suggest that there has been more out-migration among whites, or more in-migration among Negroes, or, most likely, both.

		Table 2	
	Sex Distri	bution of Sample by	Race
Sex	White	Negro	Total
Male	45.65%	42.96%	43.34%
Female	54.34%	57.03%	56.65%
N	46	277	323

As would be expected, most of the people in the households in the sample were parts of the nuclear family of the head of the household. Fewer than 15 percent were not members of the nuclear family. Relatives of a younger generation constitute about 7.5 percent of the sample, indicating an occasional occurrence of multi-generational families. It is somewhat surprising that over 27 percent of the individuals (or over 55 percent of the households) live in one or two person households. The average household size for the sample is 3.0 persons. Among the white households this is 2.3 and for the Negro, 3.2. Among the whites, 70 percent of the households contain one or two individuals (or 41 percent of the people), while 50 percent of the Negro households are this small (representing 25 percent of the people).

The average age in the sample population is 31.8. This is a little older than the general population. However, there is a substantial race difference, the Negro average being 30.6 and the white 39.3. This age difference is quite obvious at the upper and lower extremes of the age distribution. In the white population, 19 percent is under age 14, while 29 percent of the Negro population is in this youngest group. At the other extreme, 32.6 percent of the white population is 60 years old or older, while only 14.4 percent of the Negro population is this old. This certainly suggests that the age related health problems of the two racial groups will be different.

In the sample as a whole, 28 percent of the people age 15 and over have never been married, with no difference between races (27 percent of whites; 28 percent of Negroes). There are some distinct differences between the races, however, in the present status of the 72 percent who have been married. Almost half (48 percent) of the whites who have been married are

Table 3

now widowed, while only 21 percent of the Negroes are widowed. The races are approximately equal on the voluntary dissolution of marriage (divorce or separation) (15 percent of whites ever married and 18 percent of Negroes). There are, however, differences between the races in the method of dissolution, divorce being more frequent among whites (11 percent for whites, 8 percent for Negroes) and separation more frequent among Negroes (11 percent for Negroes, 4 percent for whites).

The average education of adults in the sample (persons age 18 and over) is 8.2 years. This is comparable to the median education of the area in 1960 (8.0 years). There are rather sizeable differences in the education levels within the race-sex groupings of the sample. The mean education

^{6.} These figures must be viewed with caution because of the relatively small number of whites in the sample.

of Negroes in the sample is 8.6 years, with only a half year's difference between males and females (8.9 and 8.4 years, respectively). However, the mean for whites in the sample is only 6.2 years with a difference between the sexes of 2.4 years (4.6 years for males and 7.0 years for females). These differences are made more apparent in looking at the percentage of the sample in the lowest education groups, i.e., those with less than seven years of school. Approxiamtely one-third of the total sample (31.3 percent) was in this lowest category. For Negroes, only 27.8 percent (28.8 percent of males and 27.1 percent of females) were in this category. However, almost half of the whites (48.5 percent) were in this lowest category, with a sizeable sex difference of 63.6 percent of the males and 40.8 percent of the females in this category.

The occupational level of the sample is consistent with considering the area as deprived. Only 6 percent of the employed people in the sample are in "white collar" occupations while over 75 percent of those reporting specific occupations are service workers or laborers. The

^{7.} Over 20 percent of the sample is classified on occupation as "Other." This is due, largely, to reporting employer rather than occupation.

racial distribution for "white collar" occupations is approximately equal, while the largest differences are in "craftsmen and operatives" and "service workers." Over half of the whites (54.5 percent) are "craftsmen and operatives" while 18.2 percent are "service workers." For Negroes, only 12.9 percent are "craftsmen and operatives" while 52.4 percent are "service workers."

The households in the sample are almost equally divided between male and female "heads of household" (52.8 percent male, 47.2 percent female). Among Negro households, the proportion of male heads is somewhat higher, at 58.0 percent. There is a large proportion of white households headed by females (70.0 percent) which is consistent with the large number of widows.

The male heads of households are better educated than adult males of the sample, though the difference for Negro heads is slight (9.1 years for heads and 8.9 years for the sample). The average education of white male heads is over to years more than the sample white males, 6.8 years compared to 4.6 years. In both races, female heads have less education than the adult females of the sample. For white female heads this difference is slight, 6.8 years for heads and 7.0 years for the sample. The difference for Negro females, however, is almost two years, the heads having an average of 6.5 years and the sample an average of 8.4 years.

Due largely to the female heads of households, over 17 percent of the heads do not work. This ranges from 64.5 percent of white female heads not employed to none of the white mele heads. For Nagroes, 2.0 percent of the male heads are not employed, while almost one-fourth of the female heads are not employed. For those heads of households who report an occupation, the distribution does not differ significantly from that of the sample as a whole. In spite of their higher educational level, in general the Negro heads of households, as for the whole sample, are more likely to be found in the lower occupational categories of service workers and laborers.

The sample, as the population from which it was selected, shows a very limited amount of variation of characteristics. There is, of course, variation of age and sex, but beyond this it is relatively homogeneous aggregate.

CHAPTER III

Health Problems and Reaction⁸

In attempting to obtain an overview of the population's perception of its state of health, an index of illness occurrence was computed for each household. This index is based on eleven questionnaire items which were designed to develop individual complaints in the past twelve months. The total number of positive responses for the household, divided by the number of individuals in the household is the index of illness occurrence, or average number of complaints per person. This index has a theoretical range between 0.00 and 11.00. The actual range was between 0.00 and 6.00.

The average index for all households in the sample is 1.40. Three-fourths of the households had some complaint in the past twelve months. Slightly over one-fifth of the households (21.3 percent) had an index greater than 2.00 or, in other words, on the average there were more than two complaints per person in the past twelve months. In 32.4 percent of the households the index was between .01 and 1.00 and 22.3 percent, between 1.01 and 2.00. While the index certainly cannot be used in a qualitative context, it does indicate that in a significant number of households there were several health complaints in the past year.

The average household index for white households in the sample is 2.39 and for Negro 1.17. This is, no doubt, in part a reflection of the age difference of the two races in the sample. The occupation of the

^{8.} The analysis of the health states of the population will, of necessity, be limited to internal descriptions and comparisons. Because there are no comparably obtained data for other groups this method must suffice.

^{9.} The questionnaire items on which this is based and the corresponding Code Manual entries are as follows: 2a (Code Manual 1-27), 3a (1-51), 3b (2-27), 3c (2-45), 4 (3-45), 5a (4-27), 5b (4-51), 5c (5-27), 5d (5-48), 6a (6-27), and 6b (6-48).

head of the households does not have a startling effect on the index, except, in those households in which the head is a housewife. The average index for housewife-headed households is 1.99 and for all others 1.28. This is particularly interesting in that households headed by housewives are likely to represent a more extreme portion of the deprivation index. When the household index is controlled for education the following distribution is obtained:

Table 10

Household Index of Illness Occurrence and Education of Head of Household

			ducation of 8-11	f head 12 and over
Average Index	1.93	1.79	1.01	1.14
N	25	20	40	18

This distribution certainly suggests that education level of the head is related to the occurrence of illness in the household. When the education variable is dichotomized, this fact becomes more apparent with an index of 1.87 for education level 0 through 7 and 1.05 for 8 and over.

North Nashville Illness

From the responses obtained from multiple questioning, it is apparent that the population's perception of its illness involves major problems. 10 The majority of complaints are concerned with major organs and body systems and not ill defined symptoms. As is indicated in Table 11, there are no

^{10.} The analyses involving illness are derived from the combination of the following questionnaire items: 2a (Code Manual 1-30), 3a (1-54), 4 (3-48), 5a (4-30), 5b (4-54), 5c (5-30). The relationships of age to illness, cause and treatment are not covered in the text but are included in tabular form in Appendix D.

N	63	134

major differences between the races in the illness distribution when the broad categories are used. As would be expected, because of the differences in the age composition of the two racial categories, diseases of infancy and childhood and complaints associated with pregnancy and childbirth are confined to Negroes. While the data are not shown in the table, there are two interesting differences between the races within the broad category of major organs and body systems. Complaints associated with blood, blood forming organs and circulatory system comprise 15.7 percent of the complaints among Negroes, while for whites comparable complaints comprised only 7.9 percent of the total. On the other hand, one-third of the white complaints concerned digestive and genito-urinary systems while this represented less than one-tenth of the Negro complaints.

The sexual distribution of illnesses (see Table 12) does not show any unexpected differences except in the major organs and systems category. These represent 46.9 percent of the female complaints and 62.7 percent of the male. This is an especially large difference in view of the fact that female complaints, overall, are twice as frequent as male.

Table 12 Reported Illnesses by Sex Female Male Illness 7. 7. Diseases of Infancy and Childhood 5.4 6.0 Diseases and Disorders of Skin, cellular tissue, 12.0 bones and organs of movement 17.7 Major organs and systems 46.9 62.7 Allergies, congenital and othe. 19.2 9.0 3.1 Pregnancy and childbirth Mental, psychoneurotic and personality disorders .8 3.0 Accident, poisoning and violence 5.4 7.5 Other 1.5 N 130 67

The most frequently mentioned cause of illness was associated discreters followed by "cause unknown." These two accounted for almost three-fourths of the responses given to the "cause" questions. As shown

^{11.} The analyses of causes of illness are taken from the combination of the following questionnaire items: 2a (Code Manual 1-36), 3a (1-60), 4 (3-54), 5a (4-36), 5b (4-60), 5c (5-36).

in Table 13, associated disorders represented 53.4 percent of the causes reported by whites and 36.4 percent of causes reported by Negroes. Unknown cause was the response of 35.5 percent of Negro responses, but only 19.0 percent of white responses. The major difference between the sexes with regard to cause is related to associated disorders, as is shown in Table 14. This response was used for one-half of the female responses, but only one-fourth of the male.

Treatment of Illnesses

From the multiple questions designed to develop the treatments employed for various illnesses (see Table 15, A and B), 12 the most frequent response was consultation with a doctor, clinic or hospital with no treatment indicated. 13 The second response, in frequency, was home remedies, and the third, hospitalization. Home remedies are most frequently employed for diseases of childhood and infancy, this being the

^{12.} Tables 15A and 15B are based on the same cell frequencies. They differ in the base used for computing the percentages. Table 15A is percent of illnesses using each treatment and Table 15B is percent of treatments employed for each illness.

^{13.} The analyses of treatments are taken from the combination of the following questionnaire items: 2a (Code Manual 1-39), 3a (1-63), 4 (3-57), 5a (4-39). Questions 3e, 5b, 5c, and 5d were also used with treatment implied in the questions.

indicated treatment in over half of the responses. It is interesting to note that none of the questions with regard to treatment developed a response which was categorized as "semi-medical" or "non-medical."

In analyzing the treatment responses within the demographic variables of age, race, and sex, there are very few patterns of differences worthy of note. The single exception is the apparent sharp increase of prescribed medication for persons age fifty and over. Medication, in the total distribution, comprises less than 3 percent of the responses, but for the three oldest age groups the distributions are 24.2 percent, 15.2 percent, and 27.3 percent, respectively.

Throughout the analysis, it will be apparent that limited differences associated with socio-economic status can be demonstrated. This is due, in large measure, to the relative homogeneity of the population on the two variables aimed at status, occupation of head of household and education of head of household. The treatment data do suggest, however, that as occupational status decreases, there is a greater tendency to use home remedies or do nothing about illnesses. However, since these were not frequently mentioned by any group, the tendency is not strong.

Payment for Treatment

In analyzing responses as to the payment for treatment, it was found that in 44 percent of the cases the treatment obtained was not paid for by the respondents. 14 This is based on responses to the questions which as 1 'Did you pay for these services or treatments?" The most frequent payment

^{14.} The analyses of "payment-nonpayment" are taken from the combination of the following questionnaire items: 2a (Code Manual 1-42), 3a (1-66), 3b (2-36), 3e (3-36), 4 (3-60), 5a (4-42), 5b (4-63), 5c (5-39), 5d (5-57).

for treatment was for consultation, but this occurred only 60.2 percent of the time. Hospitalization was paid for 34.8 percent and "other treatments," 37.5 percent.

The racial difference on "payment-nonpayment" is one of the strongest associations in the data. For whites, payment was made only 26.2 percent of the time, while for Negroes, payment was made 62.1 percent of the time. There are, of course, many interpretations which can be placed on these figures and later analysis will help shed some light. However, any interpretation must be based on one, or a combination, of the following four assumptions: 1) Negroes in North Nashville are better able to pay for services than are whites; 2) there are more free services available to whites than to Negroes; 3) whites are more aware of free services than are Negroes; 4) Negroes are less willing than whites to avail themselves of free services.

The distribution of non-payment by age presents an interesting curvilinear relationship (see Table 16). The highest percentage of non-payment is for school age children, between 5 and 14 years of age, where two-thirds of services obtained are not paid for by the patient. For the youngest age group, under age five, non-payment occurs in only one-third of the responses. The distribution drops to 29.3 percent for age 30-39 and rises from that point to 58.8 percent for persons age 70 and over. This distribution suggests that convenience of a service, as with an "in school" population, is an extremely important factor in its use.

The occupation of the head of household does not present as strong a relationship as might be expected, but the trend, as shown in Table 17, is certainly consistent. It is apparent from this table that the plight of

Table 16 . Payment for Services by Age

those households which are headed by housewives cannot be over-emphasized.

This is the only occupational group in which non-payment occurs more frequently than payment.

When payment was not made by the user of services, in 62.3 percent of the cases, private assistance was given as the source of funds for services. 15 Next in order were welfare (8.0 percent), insurance (7.3 percent) and Medicare (6.6 percent). Workmen's compensation, Veterans' Administration, hospital-provided services and "other" account, in combination, for 16.8 percent of the responses. As Table 18 shows, there were large variations between the

races on the matter of payment, private assistance 16 accounting for 72.8 percent of Negro responses and only 1.6 percent of white. For thites, hospital-provided services 17 was given 38.1 percent of the time and Medicare, 38.1 percent. The distribution of means of payment suggest some interesting differences of behavior in the two racial groups. The use of Medicare is a function of difference in the age composition, though this is not believed to be the only explanation. That available means of obtaining services are differentially used is obvious.

The population of North Nashville, insofar as these data portray that population, presents a vast array of health related problems and patterns of behavior adopted in response to these problems. While these data do not permit making statements with regard to the relative frequency of occurrence of problems, they do suggest, from intuitive comparisons, that the population is well aware of the fact that they have health problems. Their responses to questions on illnesses indicate that they are not generalized complaints, but rather specific problems.

These people do not indicate from their responses that they have the means to obtain services from private sources, and they do not show a uniform use of the sources which are available. Underlying all of this is the strong probability that there are health problems which are not and cannot be articulated because of limited access to reliable sources of diagnosis. It seems reasonable to assume that this population has problems which are not manifest but nevertheless are problems.

^{16.} This category of response represents, primarily, services obtained through Centenary Methodist Community Center. There are, in addition, some cases of services provided without charge by private physicians which are included in this category.

^{17.} This was predominantly General Hospital for whites.

CHAPTER IV

The Health Ethos of North Nashville

The studies of anthropologists and sociologists have offered very good evidence that perception of illness and reaction to illness are parts of and products of specific cultures. 18 For a specific physical condition to be defined as an illness or abnormality, that condition must be severe enough to impair normal functioning and infrequent enough to be viewed as a deviation from the normal. Therefore, as Zola points out, in populations which possess widespread and almost constant infirmities, the infirmity is viewed as the norm and rarely perceived by the population as an illness.

In much the same manner, a population's culture "determines" the reactions which it will adopt in response to an illness. In order for the population to adopt any specific response behavior the following sequence must be followed. First, in the case of health related responses, individuals must perceive the condition as being sufficiently abnormal and severe to warrant behavior. Secondly, for a specific behavioral response, individuals must have the potential for the behavior in their total response repertoire. This means that the behavior, if not already established, must be consistent with the values of the culture and realistic in terms of the environment in a total sense - of the culture. Finally, the individuals must be able to perceive or accept some relationship between the behavioral response and the specific health state in question. If they cannot accept in either a scientific, trusting, faithful or superstitious context the appropriateness of the behavior, there will be no reason for its adoption.

^{18.} See particularly Irving K. Zola, "Culture and Symptoms - An Analysis of Patients' Presenting Complaints," <u>American Sociological Review</u>, Vol. 31 (1966), pp. 615-630, for a recent review of the literature as well as pertinent research findings.

^{*} This question was also asked for "healers" and "chiropractors." However, such a small number responded (36 and 39, respectively) that they are not included in these tabulations.

The individual respondents in the study were asked to what extent they used or relied on eight possible sources of treatment. These data are presented in Table 19. It is interesting to note that the non-medical ("healers," etc.) and semi-medical (chiropractors, etc.) sources received, primarily, no response of any sort. For those people who did respond, over 90 percent answered "very little" for both sources. Clearly the most common

sources of assistance - doctors and hospitals - are the two which, in terms of the values of the total culture, are the most reasonable. The second level of assistance - druggists and patent medicines - involves two categories which might be classified as semi-medical. The fact that a majority of respondents answered "some" or "a great deal" for these two suggests the very important role played by druggists in this neighborhood. While the differences between races with regard to the use of doctors and hospitals is not great, there is a clear indication that Negroes utilize the druggists more frequently than do the whites. This same trend is revealed with "home remedies" but in this case the use by anyone is very slight. Perhaps the most unexpected result in these data is the fact that the population seems to make very little use of public health nurses. Three-fourths of the respondents indicate that they use public health nurses very little.

Table 20

Best Place to Get Advice on Medicine by Race

Doctor	60.0	77.0	73.8
Druggist (or drugstore)	5.0	2.3	2.8
Hospital	35.0	17.2	20.6
Other		2.3	1.9
Don't know		1.2	.9
N	20	87	107

^{19.} See Earl L. Koos, <u>The Health of Regionville</u>. (New York: Columbia University Press, 1954).

In spite of the rather frequent use of druggists, as indicated in the preceding paragraph, the individual respondents did not indicate a high confidence in druggists for advice (see Table 20). Almost three-fourths of the individuals recognize physicians as the best source of advice, with a higher percentage of Negroes than whites so responding (77.0 percent for Negroes, and 60.0 percent of whites). Hospitals are the second choice for both races, with the combination of doctor and hospital responses equalling approximately 85.0 percent of the responses for both races. Since both of these sources represent professional medical sources, 1. is reasonable to view them as reflecting comparable evaluations of reliability, the difference being point of contact rather than superiority of source. While the population makes fairly extensive use of druggists, they do not recognize them as a superior source. It must be concluded that the use is a matter of access rather than choice.

Table 21
Source of Emergency Treatment by Race

Source of Treatment	White %	Negro %	Total %
Doctor	20.0	11.1	13.3

Other hospital	30.0	17.5	20.5
Other		1.6	1.2
Don't know	5.0	6.3	6.0
N	20	63	83

In response to the question on obtaining emergency services, both Negroes and whites showed a clear preference for hospitals, with 75.0 percent of the whites indicating a hospital and 80.0 percent of the Negroes (see Table 21). The second choice category for both races was a doctor, with whites more likely than Negroes to name this source (20.0 percent of whites and 11.1 percent of Negroes). The most interesting point in these data is the very clear racial difference on specific hospital. In spite of its proximity to the area, Hubbard Hospital was not mentioned by any of the white respondents. Almost half of them (45.0 percent) named General Hospital and 30.0 percent named some other hospital. 20 For Negroes, Hubbard Hospital was clearly the preference, with 61.9 percent giving this response and other hospitals equalling 19.1 percent. 21 In the reasons for these choices (see Table 22), some explanation for these differences becomes apparent. For Negroes, convenience was the primary factor (48.1 percent) with familiarity being the next consideration (20.4 percent). On the other hand, familiarity was the primary factor for whites (52.6 percent) with competence next (21.0 percent). For whites, even in case of emergency, the choice based on convenience was the case in only 5.3 percent of the responses. Whites cited monetary reasons in 15.8 percent of the responses while Negroes did so in only 7.4 percent.

In making use of formal medical facilities, approximately one-fourth of the respondents report some problem with transportation and approximately the same proportion report problems with having to wait too long (see Table 23). Problems with waiting are reported much more frequently for whites

^{20.} Baptist Hospital, 5.0 percent; St. Thomas Hospital, 5.0 percent; and Vanderbilt Hospital, 20.0 percent.

^{21.} General Hospital, 1.6 percent; Memorial Hospital, 1.6 percent; Vanderbilt Hospital, 11.1 percent, and hospital (not specified), 4.8 percent.

N	19	54	73

(60.0 percent) than Negroes (20.0 percent). Other problems are reported by only 14.3 percent of the respondents. While problems in obtaining services do not appear to be a serious impediment, the fact that one out of four report a problem which can be reduced - transportation - should not be overlooked.

Table 23

Problems in Visiting Doctor, Hospital, Etc., by Race

	Percent* Who	Have Trouble Wi	Lth
		Waiting	
	Transportation	Too Long	Other
	%	%	%
White	30.0	60.0	31.6
Negro	25.0	20.0	10.1
Total	25.9	27.6	14.3
	(108)	(105)	(98)

^{*} Percentages are derived from three separate questions and do not, therefore, add to 100.0 percent.

Awareness of Facilities

In order to make use of available services, individuals must be aware of the existence or availability of such services. The data presented in Table 24 can be seen as very strong evidence of the lack of knowledge in this population. Three-fourths of the respondents were not aware of the existence of any public agencies which would offer them assistance with health problems. The figure is higher for Negroes (80.2 percent) than whites (55.0 percent). No doubt they are aware of the existence of some facilities which are in fact public supported, but if these people are not aware of the nature of the support and, therefore, the availability of services, then the knowledge is of limited, if any, value to them. Quite obviously, from these data, the mere establishment of a facility or service will do very little if such establishment is not accompanied by an extensive public information program which will reach the population to be served.

Table 24

Awareness by Race of Public Agencies That Assist With Health Problems

Know of Public Agencies That Assist?	White %	Negro %	Total %
No	55.0	80.2	75.5
Yes	45.0	19.8	24.5
N	20	86	106
· ·			

Table 25

Awareness of Health Assistance from Church by Race

Do churches help with health problems?	White %	Negro %	Total %
No	33.3	12.5	16.0
Yes	66.7	39.8	44.4
Don't know		47.7	39.6
N	18	88	106

while they are very unaware of public agencies from which they can obtain assistance, almost half (44.4 percent) of the respondents were aware of the availability of assistance from churches (see Table 25). There are, again, sizeable differences between the races, with the whites reporting more awareness of the availability from this source than did Negroes (66.7 percent for whites and 39.8 percent for Negroes). It is interesting to note in this context that 90.6 percent of the respondents (85.0 percent of whites and 92.0 percent of Negroes) are church members

Table 26
Church Membership by Race

	<u>Members</u> %	<u> 7</u>
White	85.0	20
Negro	92.0	87
Total	90.6	107

(see Table 26). Moreover, almost three-fourths of the respondents (73.8 percent) attend church service once a month or more (see Table 27). While one must go beyond the data for interpretations, it could be hypothesized that for the deprived, involvement in micro-structures, such as the church, must suffice for social satisfactions. The macro-structure of society is

Table 27
Church Attendance by Race

Frequency of Attendance	White 7.	Negro %	Total
Once a week or more	25.0	37.9	35.5
Two or three times a month	20.0	20.9	28.0
Once a month	15.0	9.2	10.3
Several times a year	15.0	11.5	12.2
Never or almost never	25.0	11.5	14.0
×	20	87	107

too removed to be a reality for involvement. Therefore, these people are more likely to be aware of services or information which emanates from micro-structures with which they are familiar. This is certainly an excessive interpretation for the data alone, but is consistent with the basic theories of communication research. 22

^{22.} See John W. Riley, Jr. and Matilda W. Riley, "Mass Communication and the Social System," in Robert K. Merton, et al., Sociology Today: Problems and Prospects (New York: Basic Books, 1959), pp. 53/-578.

As a final indication of the lack of knowledge or information which reaches this population, fewer than one-third of the respondents were aware of the existence of a child care center in the neighborhood (see Table 28). Since the area is serviced by four semi-public and eight private child care centers, ²³ there is an obvious need for more effective public education in this area.

Table 28

Awareness of Child Care Center by Race

White %	Negro %	Total %
11.8	32.3	28.2
35.3	30.9	31.8
52.9	36.8	40.0
17	68	85
	11.8 35.3 52.9	11.8 32.3 35.3 30.9 52.9 36.8

Behavioral Problems

The respondents to the questionnaire did not indicate a widespread awareness of mental, emotional or learning problems in the area (see Table 29). Only 13.0 percent (20.0 percent of the whites and 11.4 percent of the Negroes) were aware of anyone in the reighborhood who "gets upset too easily, worries too much, is moody, etc." The responses for awareness of

^{23.} See The Characteristics of the Population and the Social Services for a High Poverty Area in Nashville, Tennessee. Report prepared by Center for Community Studies, The John Fitzgerald Kennedy Center for Research on Education and Human Development, Nashville, Tennessee, February 1967, p. 113.

Table 29

Awareness of Behavioral Problems by Race

Is there anyone in this neighborhood who	Percent White	age Answer: Negro %	ing 'Yes' Total
Gets upset too easily, worries too much, moody	20.0	11.4	13.0
Acts up, is high tempered, high strung	20.0	12.4	13.8
Has problems with learning (dull, slow)	5.0	11.6	10.4

people who "'act up,' are 'high tempered,' 'high strung,' etc." were just about identical to those for the preceding question. The overall awareness of learning problems was less than the other two problems (10.4 percent), and there is more awareness among Negroes (11.6 percent) than whites (5.0 percent).

Table 30

Can Anything Be Done About Behavioral Problems by Race

Can anything be done about someone who	Percent: White 7.	Negro	Ing 'Yes' Total %
Gets upset too easily, worries too much, moody	25.0	22.0	22.4
Acts up, is high tempered, high strung	11.1	14.8	14.3
Has problems with learning (dull, slow)	25.0	16.1	16.7

The respondents to the questionnaire indicate limited awareness of assistance with these types of problems (see Table 30). For people who "get upset too easily," 22.4 percent are aware of help; for people who "'act up,' are 'high tempered,' etc.," 14.3 percent; and for those with learning problems, 16.7 percent. In this area of health, the population does not indicate a level of knowledge of what is available or possible comparable to their knowledge in other health areas. This information may be used further to clarify the relatively low percentages aware of problems in this area. Being aware of a possible solution to a problem probably increases the conscious admission of the problem or definition of a cendition as a problem. If one does not feel that a condition can be changed, it is unreasonable to dwell on a conception of the condition as an abnormality.

The people of North Nashville do not respond to health problems with the most desirable behavior possible. They do not follow courses of action which will result in the rapid and thorough resolution of problems. But this does not seem to be a situation in which they do not know what to do, but rather, one in which they do not know how to do it. A survey such as this can provide limited bases for predicting future behavior, but the data strongly suggest that in addition to needing services, these people need very much to know what is available to them and how they can make use of what is now available or may be made available in the future.

CHAPTER V

Summary

This was a project to study the perceptions of a representative sample of a low income population in North Nashville, Tennessee. The population to be sampled resided in an area which was defined by Meharry Medical College in their planning for a neighborhood health center (see Page 3). It is an area of some twenty square miles containing two hundred city blocks. General characteristics of the area and its population were described in a companion study.²⁴ The specific purposes of the project were to describe:

- 1. the demographic characteristics of the population,
- 2. the composition of households in the area,
- 3. the current health problems as perceived by respondents,
- 4. the respondents' perceptions of causes of the problems,
- 5. the responses to the problems or treatment sought,
- 6. the respondents' knowledge of facilities for treatment, and
- 7. problems in getting treatment.

The interview schedule was a semi-structured series of questions directed toward one respondent in a household, but covering all members of the household. A random sample of households was selected, and one hundred eight interviews were completed (eighty-eight Negro and twenty white households). The racial composition of the sample was more heavily represented by Negroes than was expected from the 1960 U. S. Census data

^{24.} See Center for Community Studies. Characteristics of the Population and Social Services in a High Poverty Area in Nashville, Tennessee. Nashville, Tennessee: The John F. Kennedy Center for Research on Education and Human Development, George Peabody College for Teachers, 1967.

(86 percent as compared with 72 percent). Within the sampled population, the Negro group was somewhat younger (31 vs. 39 years); the households were slightly larger (3.2 vs. 2.3 people); there were more married (44 percent vs. 27 percent), more separated (8 percent vs. 3 percent) and fewer widowed (15 percent vs. 35 percent). The mean educational level of the Negroes was higher (8.6 to 6.2 years) and their occupational levels tended to be lower than the white population. Thus, the Negro and Caucasian groups within the sample were shown to have rather different characteristics, and they were found to report different patterns of health problems and treatment sought.

The frequency of reported health problems was higher for white households, for those headed by a woman, and for those in which the head had less education. These were most likely the aging population. The most frequent type of health problem was reported for the category of major organs and systems. Blood and circulatory problems were more frequent for Negro subjects; digestive and urinary system problems were reported more frequently by white respondents. The problems tended to be specifically perceived and described.

Causes of health problems were most frequently attributed to disorders with unknown causes reported as the second most used category. Environmental factors and disease were reported with much less frequency. The treatment of choice was to consult a physician. The next two treatments were less than a fifth as frequent and were home remedies and hospitalization. Age was related to treatment type with child diseases being treated with home remedies, and individuals aged 50 and over reporting medication.

Payment (versus non-payment) by the individual for treatment was more likely for respondents in higher occupational levels, those aged 20 to 40, and Negroes. School age children and white respondents were least likely to have treatment paid for by their own resources. The source of payment was most likely from public sources for the white group and private welfare resources for Negroes.

It was observed that the behavior in response to perceived health problems can be viewed as reflective of the responses (or alternatives) available to people. In addition to doctors and hospitals being sources of help, druggists were cited as important although not so valued for advice as doctors. For emergency services, hospitals were preferred to physicians. Hospital use, in general, was determined by a differential weighing of factors by the two groups. Negro respondents listed convenience, familiarity and competence, while white subjects gave familiarity, competence and monetary cost. Both groups found transportation to be a problem in using services, and white respondents particularly mentioned waiting time as a problem when using services.

Lack of awareness of services and facilities available was noteable for all subjects. This was particularly noteworthy for behavior and learning problems, and was probably due to the lower incidence of perceived problems of these sorts.

The finding that Negro and white populations report different health problems and patterns of treatment, coupled with the descriptions of the differences, provide some beginning guidelines about the differing kinds of programs and approaches needed to adequately serve each group.

15.	Is there anyone in this neighborhood that you think has problems with learning (dull, slow, etc.)?
	Yes No Don't know
	Do you think anything should be done about it?
	Yes No Don't know
	Is there anyone in your family like this?
	Yes No Don't know
	(If "Yes") What is being done about it?
<u> </u>	
16.	Do you belong to a church? Yes No
17.	How often do you go to church?
	Once a week or more
	Two or three times a month
	Once a month
	Several times a year
	Never or almost never

18.	So far as you know, do the churches around here do anything to help people with their health problems?			
	Yes No Don't know			
19.	Is there a neighborhood or community center around here?			
	Yes No Don't know			
	(If "Yes") Do you ever go there? Yes No			
	How often?			
	Does the neighborhood center offer any help for health problems?			
	Yes No Don't know			
	(If "Yes", explain)			
	Do you think they are effective (good)? Yes No			
	Explain			
	·			
20.	Does anyone in this family have a social worker?			
	Yes No Don't know			
21.	(If "Yes" to 19) From what agency?			
22.	(If "Yes" to 19) Does this agency offer any help with health problems?			
	Yes No Don't know			

23.	(If "Yes" to 22) Have you ever used this agency for help with a health problem? Yes No (If "Yes") What was the problem? Did you think they were effective (good)? Yes No (If "No", explain)
214.	Do you know of any public agencies run by city, county, or state around here where you can get help for health problems? Yes No (If "Yes") What are they? Have you ever used any of these? Yes No How effective (how good) do you think each of these is?
25.	(Ask only if there are children under school age and if mother works.) Who takes care of the small children during the day?
= 26.	Is there any kind of child care center around here? Yes No Don't know (If "Yes") Have you ever used it? Yes No
